

Syntax and Variables

BILD 62

Objectives for today

- Confirm rules of Python syntax
 - Define three types of variables: integers, floats, and strings
 - Concatenate & slice strings
 - Determine rules for variable names
-

There are different types of programming languages, each with their own syntax, or rules.

- **Syntax:** the rules of a programming language
 - Includes punctuation, spacing, indentation, etc.
- Each language has strengths & weaknesses.
- Regardless, each language ultimately needs to communicate with the hardware of the computer, in 1's and 0's.
 - It's similar to DNA! And similar to DNA, we don't often describe it in individual base pairs. Instead we describe genes and describe DNA in a higher level way.

Syntax Rules in Python

- Python is **case sensitive**: `letsroll` \neq `LetsRoll`
- White space does not matter (e.g., line 9 or 11 below)
- Indentation *does* matter — use **tab** to indent your code
- **Indexing** (we'll come back to this later)

- Python starts indexing at 0. So if you have a list of numbers:

```
list = [ 2 , 5 , 7 , 1 , 9 , 2 ]
```

and you ask for `list[1]`, you'll get 5.

- Code that follows `#` is not read by the interpreter:

```
8 # this is a commented line!  
9  
10 print('this line will totally run.')  
11
```

Why does Python count from 0?

Programming languages like Fortran, MATLAB and R start counting at 1 because that's what human beings have done for thousands of years!

Languages in the C family (including C++, Java, Perl, and Python) count from 0 because it represents an offset from the first value in the array (the second value is offset by one index from the first value).

This is closer to the way that computers represent arrays.

Creating new variables

- Names are always on the left of the `=`, values are always on the right
- Pick names that describe the data / value that they store
- Make variable names as **descriptive** and **concise** as possible (this is an art!)
- Variables cannot be Python keywords:

```
[>>> import keyword  
[>>> print(keyword.kwlist)  
['False', 'None', 'True', 'and', 'as', 'assert', 'async', 'await', 'break', 'class', 'continue', 'def',  
 'del', 'elif', 'else', 'except', 'finally', 'for', 'from', 'global', 'if', 'import', 'in', 'is', 'lambda',  
 'nonlocal', 'not', 'or', 'pass', 'raise', 'return', 'try', 'while', 'with', 'yield']  
>>> █
```

(There are other rules for variable names....)

Python has many variable types, and each function a little bit differently.

Understanding your variable type is crucial for working with it.

Built-in simple variable types in Python

Type	Example	Description
int	x = 1	integers (i.e., whole numbers)
float	x = 1.0	floating-point numbers (i.e., real numbers)
complex	x = 1 + 2j	Complex numbers (i.e., numbers with real and imaginary part)
bool	x = True	Boolean: True/False values
str	x = 'abc'	String: characters or text
NoneType	x = None	Special object indicating nulls

Integers, strings, floats

function to convert to integer

- **Integers** (**int**): any whole number
- **Float** (**float**): any number with a decimal point (floating point number)
- **String** (**str**): letters, numbers, symbols, spaces
 - Represented by matching beginning & ending quotes
 - Quotes can be single or double; use single *within* double
 - Use \ to ignore single quote
 - Concatenate strings with +

Checking variable types

This is a very useful troubleshooting step!

- You can check what type your variable (**a**) is by using **type(a)**
 - Alternatively, we can use:

```
>>> type(a) is float
```

or

```
>>> isinstance(x, float)
```
- Python lets you change the type of variables, however, ***you cannot combine types.***
- Use **del** to delete variables

It's important to know the precision of your variables.

In most datasets, we are working with floats.

Autopsy Report:

Dr. Andrew Esty

Time of Death: 03/16 11:53

Cause of Death: Rounding Errors

Let's dig in to notebook 03!

Use the [magic link](#) to sync up your DataHub with our Materials folder and open 03.

Topics from today

- Assigning variables & rules for variable names
- Types of objects we met: integers, floats, strings
- How to **concatenate** and **slice** strings
- Functions we learned: `type`, `isinstance`, `float`, `int`, `str`
